

Release-acquire consistency: made for message passing

T1

```
// Prepare data  
data = 42;  
// Notify other thread  
flag.store(true, release);
```

T2

```
// Wait for data to be ready  
while(!flag.load(acquire)) { //  
  Spin }  
// Use data  
Foo(data); // guarantee 42
```

- **Acquire (load)** stops any operations **before** it to be reordered to after it ("Something has been done"). (force thread to flush buffer)
- **Release (store)** stops any operations **after** it to be reordered to before it. ("I want to receive message from another thread") (get all information flushed by previous threads)

May require **fewer** memory barriers than SC, but **more** memory barriers than relaxed - depends on architecture.
