

- Acquire the mutex via `std::unique_lock`
- Call `wait`, passing the lock and a predicate (Zero-argument boolean function; always a lambda in practice)

```
std::unique_lock<std::mutex> lock(mutex_);
```

```
// wait until the predicate is true
```

```
condition_.wait(lock, [...]) -> bool { return ...; };
```

```
// [...]: Capture relevant state to evaluate the predicate
```
